Rutgers University

October 24, 2018

Class Information

- HW5 posted in Sakai.
- HW6 will be posted by the end of today.
- Next week's recitation is a review for midterm. Attendance is encouraged!
- Reminder: **Midterm exam** 11/7, in class, closed book, closed notes.
Midterm covers lecture 1-12, hw 1-5, and corresponding book chapters.
- There will be extended office hours next week.
Pay attention to Sakai announcements!

Scheme - Functions as First Class Values (Higher-Order)

Functions as arguments:

```
(define f (lambda (g x) (g x) ) )
```

- (f number? 0) \Rightarrow (number? 0) \Rightarrow #t
- (f length '(1 2)) \Rightarrow (length '(1 2)) \Rightarrow 2
- (f (lambda (x) (* 2 3)) 3) \Rightarrow ((lambda (x) (* 2 3)) 3) \Rightarrow (* 2 3) \Rightarrow 6

Add WeChat powcoder

Scheme - Functions as First Class Values (Higher-Order)

Computation, i.e., **function application** is performed by reducing the initial S-expression (program) to an S-expression that represents a value.

Reduction is performed by **substitution**, i.e., replacing formal by actual parameters in the function body.

Examples for S-expressions that directly represent values, i.e., cannot be further reduced:

Assignment Project Exam Help

- function values (e.g.: `(lambda (x) e)`)
- constants (e.g.: `3`, `#t`)

Computation completes when S-expression cannot be further reduced

Review: Higher-Order Functions (Cont.)

Functions as returned value:

```
(define plusn
```

```
  ( lambda (n)
```

```
    (lambda (x) (+ n x))
```

```
  )
```

```
)
```

Return a function

Assignment Project Exam Help

- **(plusn 5)** evaluates to a function that adds 5 to its argument:

<https://powcoder.com>

Add WeChat powcoder

Question: How would you write down the value of (plusn 5)?

```
(lambda (x) (+ 5 x))
```

- **((plusn 5) 6) = ?**

Review: Higher-Order Functions (Cont.)

In general, any n -ary function

(lambda (x_1 x_2 ... x_n) e)

can be rewritten as a nest of n unary functions:

(lambda (x_1)

(lambda (x_2)

(... (lambda(x_n) e) ...)))

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

Review: Higher-Order Functions (Cont.)

In general, any n -ary function

(lambda (x₁ x₂ ... x_n) e)

can be rewritten as a nest of n unary functions:

(lambda (x₁)

(lambda (x₂)

(... (lambda(x_n) e) ...)))

This translation process is called **currying**. It means that having functions with multiple parameters do not add anything to the expressiveness of the language:

((lambda (x₁ x₂ ... x_n) e) v₁ v₂ ... v_n)

(... (((lambda (x₁)

(lambda (x₂)

...

(lambda (x_n) e)...)) v₁) v₂) ... v_n)

Review: Higher-order Functions: map

```
(define map
  (lambda (f l)
    (if (null? l)
        '()
        (cons (f (car l)) (map f (cdr l)))
    )
  )
)
```

function (points to `f`)
list (points to `l`)

Apply *f* to the first element of *l* Apply *map* and *f* to the rest of *l*

<https://powcoder.com>

Add WeChat powcoder

- **map** takes two arguments: a function **f** and a list **l**
- **map** builds a new list by applying the function to every element of the (old) list

Review: Higher-Order Functions: map

- Example:

`(map abs '(-1 2 -3 4)) ⇒ (1 2 3 4)`

`(map (lambda (x) (+ 1 x)) '(-1 2 3)) ⇒ (0 3 4)`

- Actually, the built-in **map** can have more than two arguments:

`(map + '(1 2 3) '(4 5 6)) ⇒ (5 7 9)`

Assignment Project Exam Help

Add WeChat powcoder

Review: More on Higher-Order Functions

reduce Higher order function that takes a binary, associative operation and uses it to “roll up” a list

```
(define reduce
  (lambda (op l id)
    (if (null? l)
        id
        (op (car l) (reduce op (cdr l) id)))))
```

<https://powcoder.com>

Example: (reduce + '(10 20 30) 0) ⇒
(+ 10 (reduce + '(20 30) 0)) ⇒
(+ 10 (+ 20 (reduce + '(30) 0))) ⇒
(+ 10 (+ 20 (+ 30 (reduce + '() 0)))) ⇒
(+ 10 (+ 20 (+ 30 0))) ⇒
60

Review: Higher-Order Functions

Compose higher order functions to form compact powerful functions

```
(define sum  
  (lambda (f l)  
    (reduce + ( map f l ) 0) ) )
```

Assignment Project Exam Help

```
(sum (lambda (x) (* 2 x)) '(1 2 3)) ⇒ 10
```

Add WeChat powcoder

```
(reduce (lambda (x y) (+ 1 y)) '(a b c) 0) ⇒
```

Lexical Scoping and let, let*, and letrec

All are variable binding operations:

LET = let, let*, letrec

```
(LET ( (v1 e1)
      (v2 e2)
```

```
      ...
```

```
      (vn en) )
```

```
      e
```

```
)
```

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

Lexical Scoping and let, let*, and letrec

- **let:**
 - binds variables to values (no specific order), and evaluate body e using bindings
 - new bindings are not effective during evaluation of any e_i
- **let*:**
 - binds variables to values in textual order of write-up
 - new binding e_{i-1} is effective for next e_i
- **letrec:**
 - bindings of variables to values in no specific order
 - independent **evaluations of all e_i to values** have to be possible
 - new bindings effective for all e_i
 - mainly used for recursive function definitions

let and let* example

```
( let ( (a 5) (b 6) )  
  ( + a b ) )
```

Add WeChat powcoder

Lexical (Static) Scoping

- The occurrence of a variable matches the lexically closed **binding** occurrence.
- An occurrence of a variable without a matching binding occurrence is called *free*.
- A variable can occur free and bound in an expression.

Assignment Project Exam Help

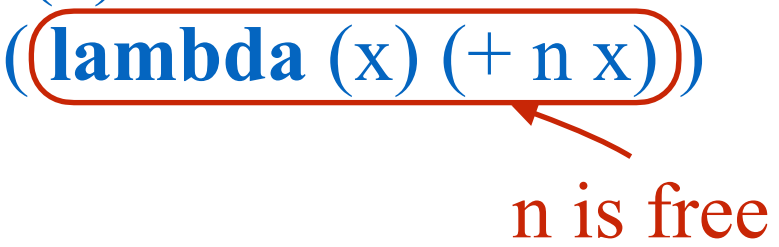

We only substitute free occurrences of the formal arguments in the function body when making a function application!

<https://powcoder.com>
Add WeChat powcoder

Free and Bound

Consider the following function definition:

```
(define plusn  
  (lambda (n)  
    (lambda (x) (+ n x))))
```

n is free

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

Free and Bound

Consider the following function definition:

```
(define plusn  
  (lambda (n)  
    (lambda (x) (+ n x))  
  )  
)
```

n is bound

Assignment Project Exam Help

Add WeChat powcoder

Environment and Closure

Environment:

- Record the bindings for the variables. If we need the value that a variable denotes, we just look it up in the environment.

An environment is a finite map from variables to values

$\rho \in \text{Env} = \text{Variables} \rightarrow \text{Values}$

<https://powcoder.com>

Add WeChat powcoder

Closures

Pair the environment with a function (lambda abstraction). The environment must contain values for all free variables of the function. The function can only be evaluated in its attached environment.

Such a pairing is called a **Closure**.

A **closure** is a pair consisting of an environment and a function definition.

<https://powcoder.com>
Add WeChat powcoder

$$cl \in \text{Closure} = \{\langle \lambda, \rho \rangle \mid \text{FreeVar}(\lambda) \subseteq \text{DOM}(\rho)\}$$

Closures can be used to implement lexical scoping.
They represent lexically scoped **function values**.

How to Apply a Closure?

How to apply a closure value to actual argument values?

- Let c_v be the closure value $\langle (\text{lambda } (x) e), \rho \rangle$
- Apply c_v to a value a_v as follows:

Evaluate the body e of the function in the environment ρ of the closure extended by the mapping of the **formal parameter** x to the **actual parameter** a_v ($\rho[x \longrightarrow a_v]$).

How to Apply a Closure: Examples

$((\text{lambda}(\mathbf{x})$
 $((\text{lambda}(z) ((\text{lambda}(x)(z\ x))\ 3)) (\text{lambda}(y)(+ x\ y)))) \mathbf{1})$

closure interpreter

$\{ \}$

$((\text{lambda}(\mathbf{z}) ((\text{lambda}(x)(z\ x))\ 3))$

$\{ x \rightarrow 1 \}$

$(\text{lambda}(y)(+ x\ y))$

Assignment Project Exam Help

$((\text{lambda}(\mathbf{x}) (z\ x))$

<https://powcoder.com>

$\{ x \rightarrow 1,$

$\mathbf{3})$

Add WeChat powcoder

$z \rightarrow \langle (\text{lambda}(y)(+ x\ y)), \{ x \rightarrow 1 \} \rangle \}$

$(z\ x)$

$\{ x \rightarrow 3,$

$z \rightarrow \langle (\text{lambda}(y)(+ x\ y)), \{ x \rightarrow 1 \} \rangle \}$

$(+ x\ y)$

$\{ x \rightarrow 1, y \rightarrow 3 \}$
